#### Zach Hill, Jie Li, Ming Mao, Arkaitz Ruiz-Alvarez, Marty Humphrey Department of Computer Science, University of Virginia

# Early Observations on the Performance of Windows Azure

# **Applications in Azure**

- The question is not can I build my application for the cloud, it's how to do it well
- How will it perform?
- Our focus
  - How do Azure services perform?
- Experiments run between November, 2009 and February, 2010

# **A Typical Application Architecture**

#### Deployment & Scaling Compute Resources

- Methodology
  - Application deployed from Azure Blob Storage
  - Deployment package <5MB</p>
  - Measure time to start deployment (i.e. 4 small instances.)
  - Measure time to double instance count
  - Between Dec 17, 2009 and Jan 09 2010 we ran the experiment 431 times. Failure rate: 2.6%

#### Deploying: 1<sup>st</sup> VM Instance Startup time

16 13.8 14 13.2 11.3 11.0 12 10.6 9.9 9.9 10 8.9 Minutes 8 Web 6 Worker 4 2 0 Small Medium Large X-Large VM Instance Size

Average Instance Adding Time

Science Cloud Workshop June 21st, 2010

# **Scaling: Adding Instances**

Scaling versus Startup for 4 Small Instances

Science Cloud Workshop June 21st, 2010

#### **Deployment & Scaling Takeaways**

- Deploying a VM takes around 10 minutes too long?
- Adding instances takes much longer than initial deployment—even worse
- Larger instance types take longer to start & web roles take longer than worker roles
- Not all instances will come online at the same time

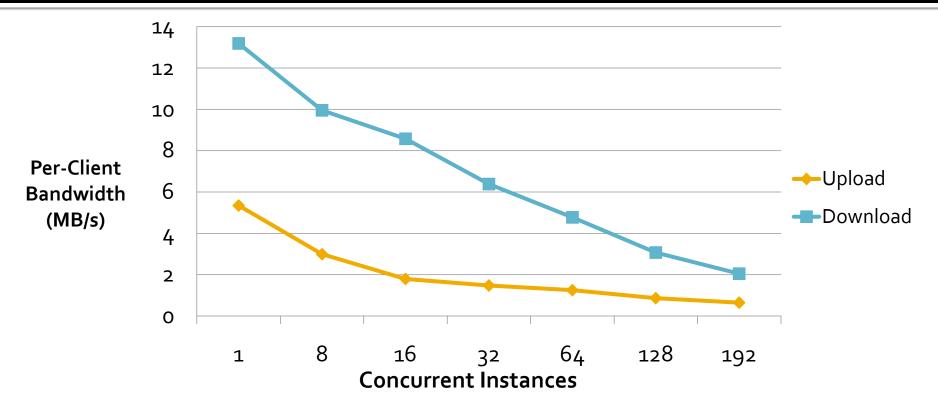

# Windows Azure Storage Services

- Blobs Large, unstructured storage
- Tables Semi-structured data, queries, updates, inserts, deletes
- Queues FIFO, asynchronous messaging

# Windows Azure Blob Service

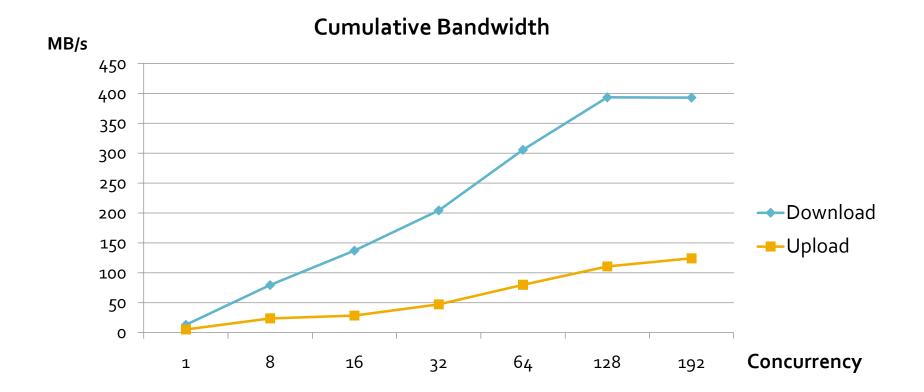

- Large object storage 50GB or 1TB limit depending on type
- Get/Put semantics
- Performance isolated between blob containers
- Methodology:
  - Get a 1GB blob concurrently with 1 192 clients operating on the same blob
  - Put 1GB blobs concurrently into same container

### Windows Azure Blob Performance at Client

- Download more than 2x upload speed
  Single, small client ~100Mb/s

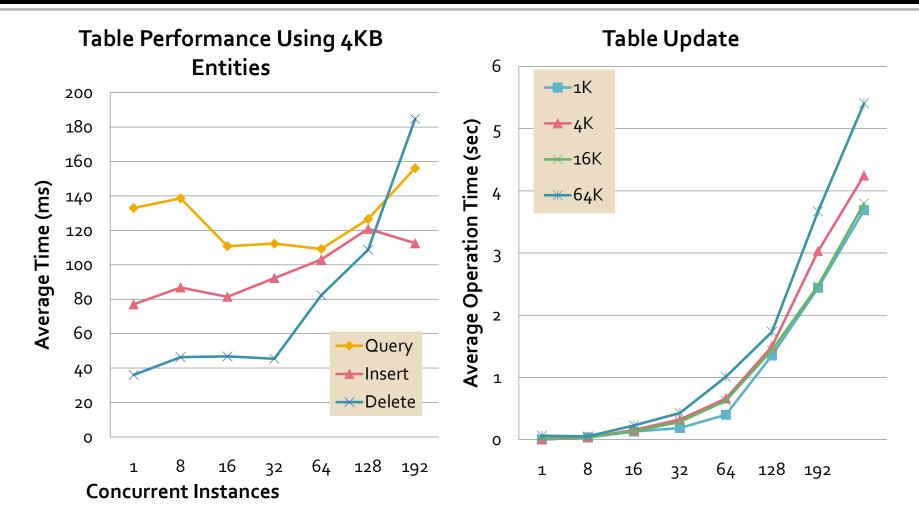

#### Windows Azure Blob Service Performance

# Windows Azure Table Service

- Entity, Attribute, Value model
- Semi-structured, no schema
- Methodology:
  - Perform 4 primary operations: insert, query, update, delete
  - Each client operates on unique entities (rows) within the same shared partition
  - Insert & Query & Delete: 500 ops/client
  - Update: 100 ops/client
  - ~220K entities in table for Query, Update, & Delete

#### Windows Azure Table Service Performance

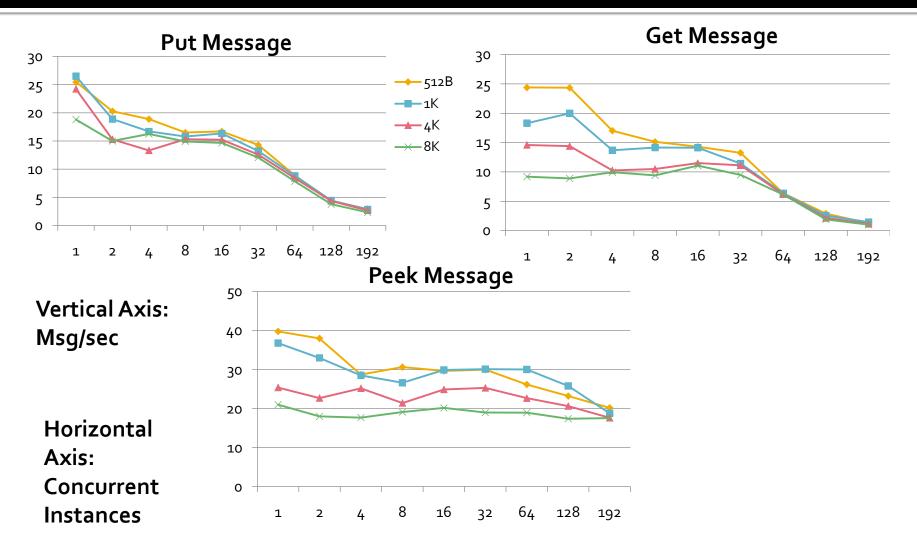

Science Cloud Workshop June 21st, 2010

# Windows Azure Queue Service

- Passing small (<=8K) messages in a FIFO style</p>
- Get, Put, Peek operations
- Methodology: Single queue, concurrent clients get/put messages

#### Windows Azure Queue Service Performance

# **Direct TCP Communication**

- TCP Endpoints allow Worker-to-Worker Role communication directly
- Offers a lower latency communication mechanism than message queues
  - No intermediary required

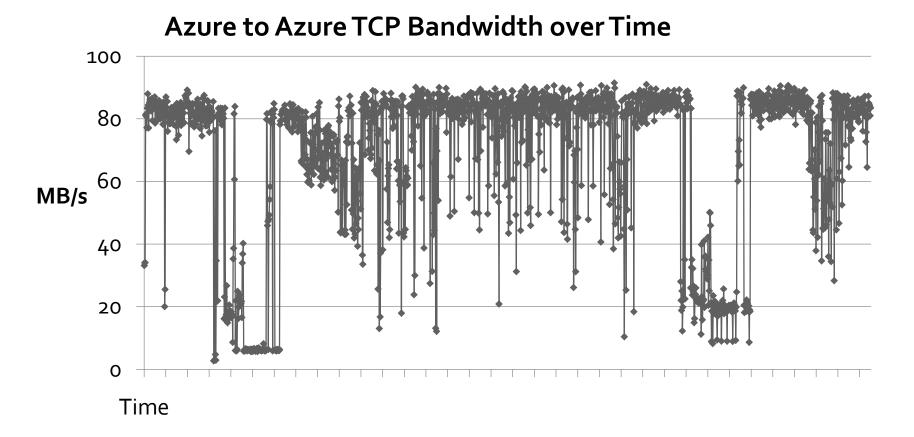

# **Worker Role TCP-Endpoints**

**Cumulative Percentage** 

**Bandwidth** Latency 100% 100% **Cumulative Percentage** 90% 90% 80% 80% 70% 70% 60% 60% 50% 50% 40% 40% 30% 30% 20% 20% 10% 10% 0% 0% ŝ **^**⁰ ଚ୍ଚ ଚ ŝ о Х  $\gamma^{0}$  $\sim^{\circ}$ ଡ 0 60 80 0 40 20 100 **MB**/sec RTT ms

#### **TCP Bandwidth Variance Over Time**

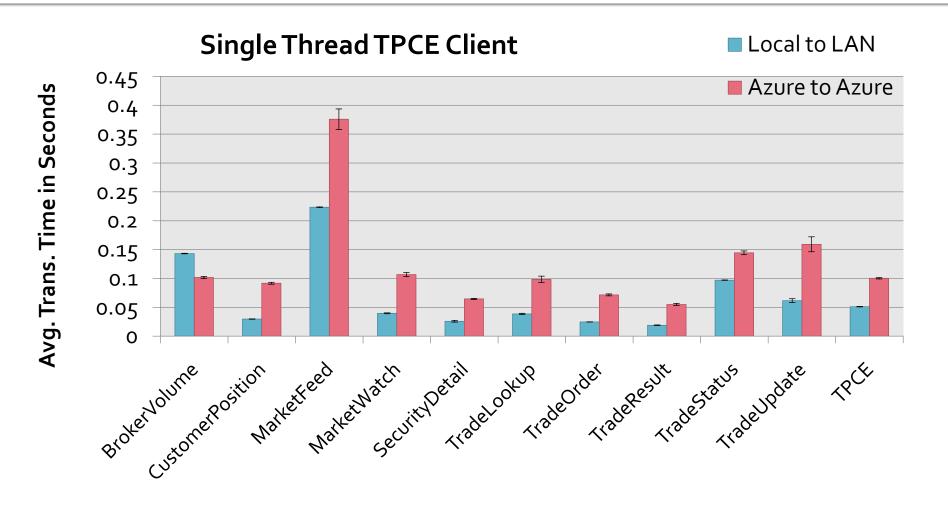

TCP performance can change dramatically, why?

### **SQL** Azure

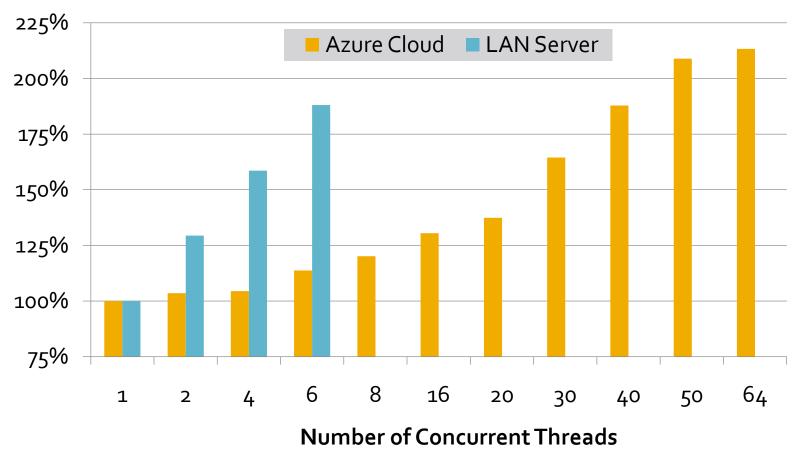

- Normal SQL Server capabilities (RDBMS)
- Size limited to <50GB per database</p>
- Tested with TPC-E benchmark for OLTP workload
  - Our .NET implementation of the benchmark
  - Simulates a brokerage house
  - Testing DB is 3GB in size

#### **SQL Azure Performance**

# SQL Azure Scaling (I)

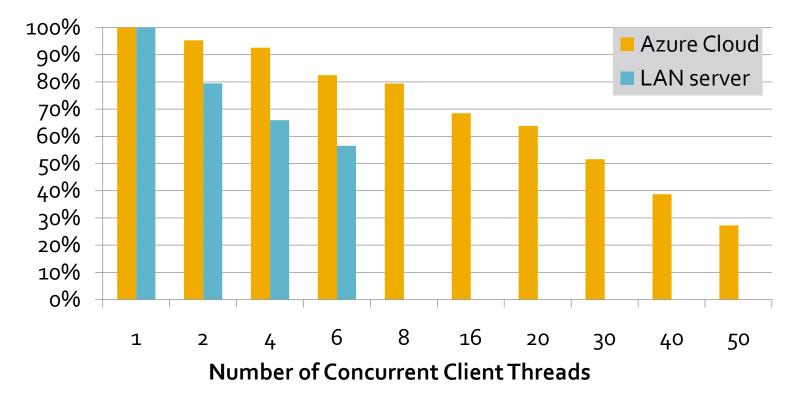

Normalized average TPCE transaction time (only committed transactions)

Science Cloud Workshop June 21st, 2010

# SQL Azure Scaling (II)

Normalized Percent of Transactions Committed per Client Thread

Science Cloud Workshop June 21st, 2010

# General Recommendations & Conclusions

- Deployment size → expected client slowdown and service throughput
- Deployment scaling is slower than initial deployment, web roles slower than worker roles, large VMs slower than small VMs
- VM deployment can take a long time depending on how many are requested
- Distribute blob accesses across as many containers as possible to achieve performance at scale

#### General Recommendations & Conclusions (II)

- Access tables by partition and row key. Property filters are slow
- Tables scale well for query and insert, but watch out for delete and update – this is expected
- Expect SQL Azure 2x slowdown
- SQL Azure scales reasonably well, especially under 30 or less concurrent clients
- SQL Azure performance over time: low variability
